**The second-order system is 2 independent energy storage**

## Overview

---

We recall from Section 2.1.2 that a second-order system is a dynamical system in which two variables are required and sufficient to describe the storage of position (linear or angular), velocity (or momentum), energy, mass, etc. How is energy stored in a second order system?

In case of mechanical second order systems, energy is stored in the form of inertia whereas in case of electrical systems, energy can be stored in a capacitor or inductor. We analyze the responses in second order systems in undamped, under damped, critically damped and over damped cases. Let us have a look on these: 1.

What is an example of a second-order energy storage system?

Typical examples are the spring-mass-damper system and the electronic RLC circuit. Second-order systems with potential oscillatory responses require two different and independent types of energy storage, such as the inductor and the capacitor in RLC filters, or a spring and an inert mass.

Are higher order systems based on second order systems?

Higher order systems are based on second order systems. In case of mechanical second order systems, energy is stored in the form of inertia whereas in case of electrical systems, energy can be stored in a capacitor or inductor. We analyze the responses in second order systems in undamped, under damped, critically damped and over damped cases.

What is a second order system?

Second order systems, like first order systems, are an extremely important class of systems. In previous chapters, we saw that the natural response of first order systems decays exponentially with time - the natural response decays monotonically to zero. The natural response of second order systems ca
